## INTRODUCTION

---

Corn agronomy at the Department Plant and Agroecosystem Sciences, UW-Madison marked the 52nd year of successful corn hybrid performance evaluation trials. Hybrid performance evaluation is critical to hybrid selection which is an important decision made by the growers. It is also crucial for delivering new technologies, pest resistance and increased yield benefit and profitability. The purpose of these trials is to provide an unbiased performance comparisons of hybrid seed corn for grain and silage available in Wisconsin.

In 2024, grain and silage performance trials were planted at 12 locations in four production zones: the southern, south central, north central, and northern zones. The hybrids used were submitted by both seed companies and university researchers. Companies that participated in 2024 are listed in Table 1. The names of the hybrids and test location is provided in table 2. A summary of transgenic traits tested in 2024 is listed in Table 3. A summary of seed treatments performance is given in Table 4. At most locations, trials were classified as early- and late-maturity trials based on the hybrid relative maturities as listed by seed companies. The specific relative maturities separating early from late trials are listed in the tables.

### Growing Season 2024 Summary

The growing season 2024 at most of the trial sites started with average temperatures closer to and rainfall higher than 30-year normal for Growing Degree Unit (GDU) accumulation and precipitation. Nonetheless, for most of the trials planting progress was ahead of the state average with ten out of 12 trials (>80%) planted by May 10. All trial plots were established by early May. Stand establishment was good to average with rainfall higher than the 30-year normal between April 20th to May 30th leading to some flooding and emergence issues. By mid- to late growing season, rainfall became more sporadic with July, August, and September receiving lower rainfall than 30-year normal for most of the state except in central Wisconsin. Overall, the accumulated rainfall for the entire growing season (April 20-October 31) was closer to 30-year normal. Disease and insect pressure were minimal at most trials, except for some reported incidence of tar spot and southern corn rust in Southern and Central Wisconsin. Trials at Hancock showed a very high incidence and severity of Tar spot, resulting in early season drying of the crop and lower than average moisture levels at harvest. Overall, good growing conditions continued into late-fall with a killing frost occurring in late October and the harvest being ahead of the state average.

### Cultural Practices

The seedbed at each location was prepared by either conventional or conservation tillage methods. Seed treatments of hybrids entered into the trials are described in Table 4. Fertilizer was applied as recommended by soil tests. Herbicides were applied for weed control and supplemented with cultivation when necessary. Corn rootworm insecticide was applied in all trials. Information on cultural practices for each location is summarized in Table 6.

## **Planting**

A precision vacuum corn planter using GIS technology was used at all locations except Spooner. Two-row plots, 25 feet long, were planted at all locations. Plots were not hand-thinned. Each hybrid was grown in at least three separate plots (replicates) at each location to account for field

## **Harvesting**

**Grain:** Two-row plots were harvested with a self-propelled corn combine. Lodged plants and/or broken stalks were counted, plot grain weights and moisture contents were measured, and yields were calculated and adjusted to 15.5% moisture. Test weight was measured on each plot.

**Silage:** Whole plant (silage) plots were harvested using a tractor-driven, three-point mounted one-row chopper. One row was analyzed for whole-plant yield and quality. Plot weight and moisture content were measured, and yields were adjusted to tons of dry matter per acre. A sub-sample was collected and analyzed using near infrared spectroscopy.

## **PRESENTATION OF DATA**

---

Yield results for individual location trials and for multi-location averages are listed in Tables 7 through 22. Within each trial, hybrids are ranked by moisture averaged over all trials conducted in that zone during 2024. Yield data for both 2023 and 2024 are provided if the hybrid was entered in both years. Starting in 2009, a nearest neighbor analysis of variance for all trials as described by Yang et al. (2004, *Crop Science* 44:49–55) and Smith and Casler (2004, *Crop Science* 44:56–62) is included. A hybrid index (Table 2) lists relative maturity ratings, specialty traits, seed treatments, and production zones tested for each hybrid.

### **Relative maturity**

Seed companies use different methods and standards to classify or rate the maturity of corn hybrids. To provide corn producers a “standard” maturity comparison for the hybrids evaluated, the average grain or silage moisture of all hybrids rated by the company’s relative maturity rating system are shown in each table as shaded rows. In these Wisconsin results tables, hybrids with lower moisture than a particular relative maturity average are likely to be earlier than that relative maturity, while those with higher grain moisture are most likely later in relative maturity. Company relative maturity ratings are rounded to 5-day increments.

The Wisconsin Relative Maturity rating system for grain (GRM) and silage (SRM) compares the harvest moisture of a grain or silage hybrid to the average moisture of company ratings using linear regression. Each hybrid is rated within the trial and averaged over all trials in a zone. Maturity ratings (company, GRM, and SRM) can be found in Table 2.

### **Grain performance index**

Three factors—yield, moisture, and standability—are of primary importance in evaluating and selecting corn hybrids. A performance index (PI), which combines these factors in one number, was calculated for multi-location averages for grain trials. This index evaluates yield, moisture, and lodged stalks at a 50 (yield): 35 (moisture): 15 (lodged stalks) ratio.

The PI was computed by converting the yield, moisture (dry matter), and upright stalk values of each hybrid to a percentage of the test average. Then the PI for each hybrid that appears in the tables was calculated as follows:

$$\text{Performance Index (P.I.)} = [(\text{Yield} \times 0.50) + (\text{Dry matter} \times 0.35) + (\text{Upright stalks} \times 0.15)] / 100$$

### Silage performance index

Corn silage quality was analyzed using near infrared spectroscopy equations derived from previous work. Plot samples were dried, ground, and analyzed for crude protein (CP), acid detergent fiber (ADF), neutral detergent fiber (NDF), in-vitro cell wall digestibility (NDFD), in-vitro digestibility (IVD), and starch. Spectral groups and outliers were checked using wetchemistry analysis

The **MILK2006** silage performance indices, milk per ton and milk per acre, were calculated using an adaptation by Randy Shaver (UW-Madison Department of Dairy Science) of the MILK91 model (Undersander, Howard, and Shaver; Journal Production Agriculture 6:231–235). In MILK2006, the energy content of corn silage was estimated using a modification of a published summative energy equation (Weiss and coworkers, 1992; Animal Feed Science Technology 39:95–110). In the modified summative equation, CP, fat, NDF, starch, and sugar plus organic acid fractions were included along with their corresponding total-tract digestibility coefficients for estimating the energy content of corn silage. Whole-plant dry matter content was normalized to 35% for all hybrids. The sample lab measure of NDFD was used for the NDF digestibility coefficient.

Digestibility coefficients used for the CP, fat, and sugar plus organic acid fractions were constants. Dry matter intake was estimated using NDF and NDFD content assuming a 1,350-pound cow consuming a 30% NDF diet. Using National Research Council (NRC, 2001) energy requirements, the intake of energy from corn silage was converted to expected **milk per ton**. **Milk per acre** was calculated using milk per ton and dry matter yield per acre estimates (Schwab, Shaver, Lauer, and Coors, 2003; Animal Feed and Science Technology 109:1–18).

### Least significant difference

Variations in yield and other characteristics occur because of variations in soil and growing conditions that lower the precision of the results. Statistical analysis makes it possible to determine, with known probabilities of error, whether a difference is real or whether it might have occurred by chance. Use the appropriate least significant difference (LSD) value at the bottom of the tables to determine true differences.

Least significant differences at the 10% level of probability are shown. Where the difference between two selected hybrids within a column is greater than or equal to the LSD value at the bottom of the column, you can be sure in nine out of ten cases that there is a real difference between the two hybrid averages. If the difference is less than the LSD value, the difference may still be real, but the experiment has produced no evidence of real differences. Hybrids that were not significantly lower in performance than the highest hybrid in a particular test are indicated with an asterisk (\*).

## HOW TO USE THE RESULTS

---

The results provide you with an independent, objective evaluation of the performance of unfamiliar hybrids that seed company sales representatives are promoting, as well as a comparison of these unfamiliar hybrids with competitive hybrids. Below are suggested steps to follow for selecting top performing hybrids for next year using these trial results:

1. **Use multi-location average data in shaded areas.** Consider single location results with extreme caution.
2. Begin with trials in the zone(s) nearest you.
3. Compare hybrids with similar maturities within a trial. You will need to divide most trials into at least two and sometimes three groups with similar average harvest moisture—within about a 2% range in moisture.
4. Make a list of five to 10 hybrids with highest 2023 performance index within each maturity group within a trial.
5. **Evaluate the consistency of the performance of the hybrids on your list** over the years and in other zones.
  - a. Scan the 2024 results. **Be wary** of any hybrids on your list that had a 2024 PI of 100 or lower. Choose two or three of the remaining hybrids that have relatively high PIs for **both** 2024 and 2023.
  - b. Check to see if the hybrids you have chosen were **entered in other zones**. (For example, some hybrids entered in the Southern Zone Trials, Tables 7 and 8, are also entered in the South Central Zone Trials, Tables 9 and 10.)
  - c. **Be wary** of any hybrids with a PI of 100 or lower for 2024 or 2023 in any other zones.
6. Repeat this procedure with about three maturity groups to select top-performing hybrids with a range in maturity in order to spread weather risks and harvest time.
7. Observe the relative performance of the hybrids you have chosen based on these trial results in several other reliable, unbiased trials and be wary of any with inconsistent performance.
8. Consider including the hybrids you have chosen in your own test plot, primarily to evaluate the way hybrids stand after maturity, dry-down rate, grain quality, or ease of combine shelling or picking.
9. Remember that you don't know what weather conditions (rainfall, temperature) will be like next year. Therefore, the most reliable way to choose hybrids with greatest chance to perform best next year on your farm is to consider performance in both 2024 and 2023 over a wide range of locations and climatic conditions.

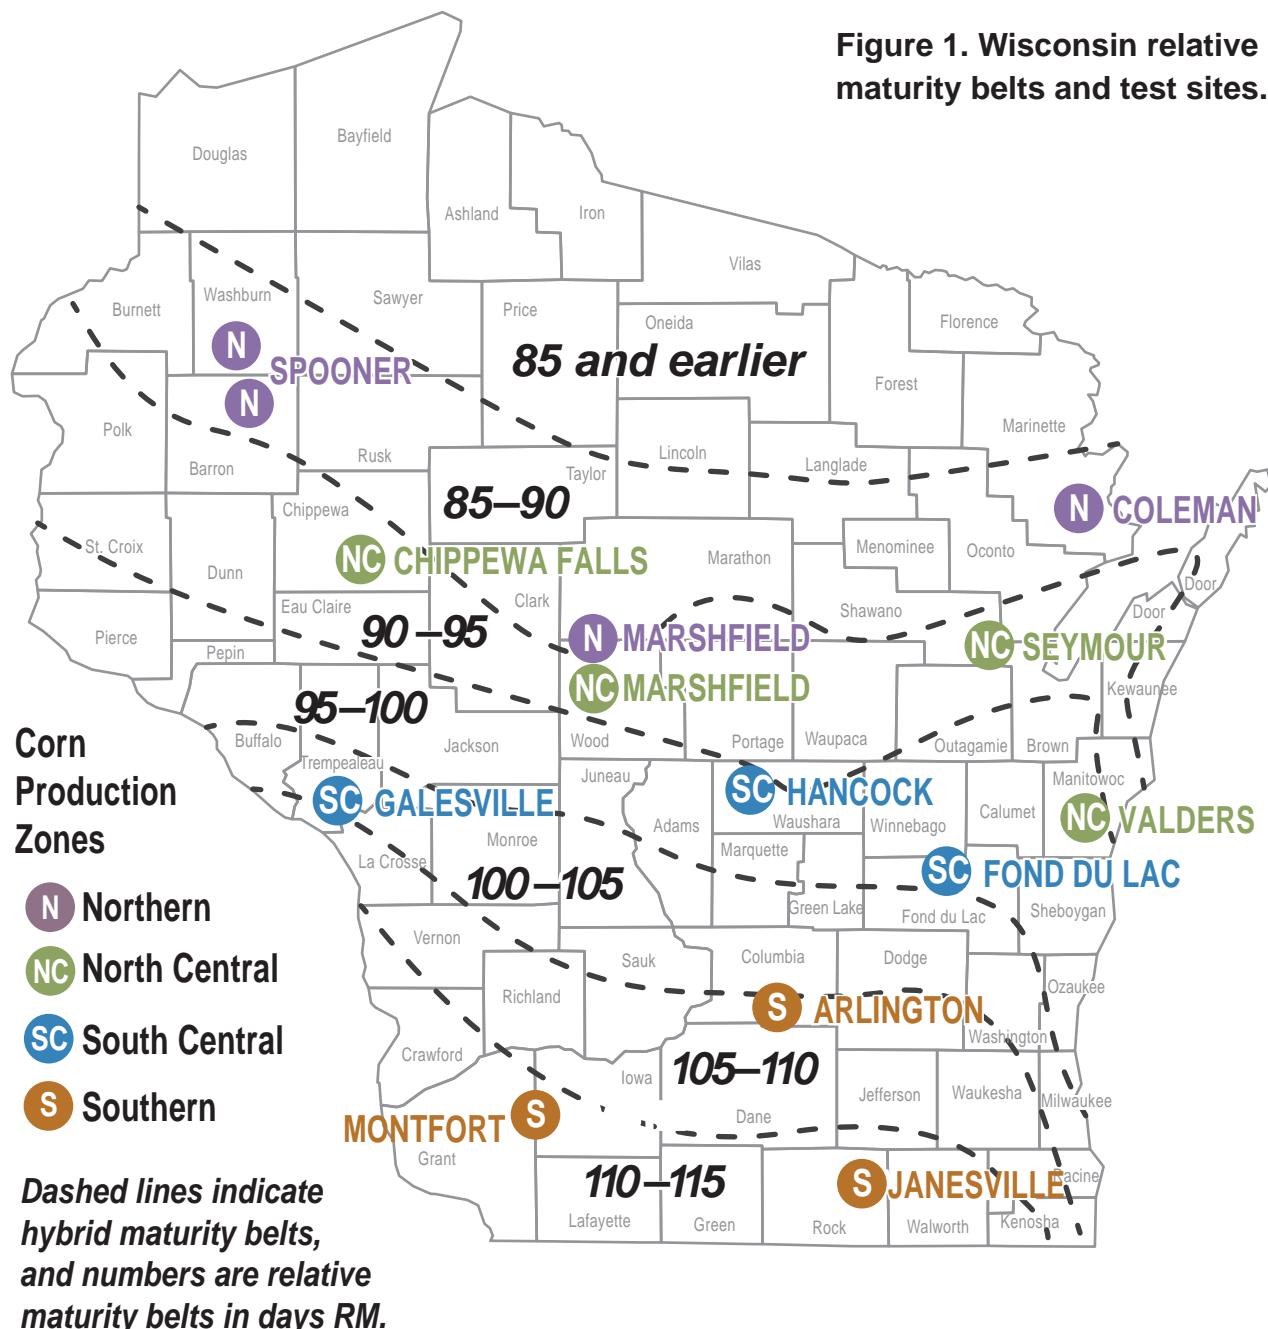

**Note:** You are taking a tremendous gamble if you make hybrid selection decisions based on 2024 yield comparisons in only one or two local test plots.

## **FOR MORE INFORMATION**

---

Current and past versions of *Wisconsin Corn Hybrid Performance Trials* (A3653) are available in Microsoft Excel and Acrobat PDF formats at the Wisconsin Corn Agronomy website: [corn.agronomy.wisc.edu](http://corn.agronomy.wisc.edu). To obtain a printed copy, visit UW-Extension's Learning Store at [learningstore.uwex.edu](http://learningstore.uwex.edu), where the most current version of *Wisconsin Corn Hybrid Performance Trials* (A3653) can be ordered or downloaded. For more information on the Wisconsin Crop Improvement Association, visit: [wcia.wisc.edu](http://wcia.wisc.edu).

#### Trait references

References to transgenic traits in this publication are for your convenience and are not an endorsement or criticism of one trait over other similar traits. Every attempt was made to ensure accuracy of traits in the hybrids tested. You are responsible for using traits according to the current label directions of seed companies. Follow directions exactly to protect the environment and people from misuse. Failure to do so violates the law.

## Average whole plant moisture of all hybrids in the trial as rated by the participating company maturity rating systems. Ratings are rounded to 5 day increments.

\* Hybrids that performed statistically similar to the highest hybrid in the trial.

Shaded results provide the best estimate of relative hybrid performance.

**Figure 3. Relationship between Milk per Acre and Milk per Ton of corn hybrids in South Central Wisconsin during 2024. A bolded hybrid performed statistically similar to the highest hybrid for Yield, Milk per Ton and Milk per Acre.**

**Authors:** Kent Kohn is corn program manager, Thierno Diallo is senior research specialist, and Harkirat Kaur is an assistant professor, Department of Plant and Agroecosystem Sciences College of Agricultural and Life Sciences, University of Wisconsin–Madison. Kaur also holds an appointment with University of Wisconsin, Division of Extension. Division of Extension publications are subject to peer review.

**Acknowledgment:** The Corn Agronomy Program would like to extend our heartfelt gratitude to Dr. Joe Lauer for his invaluable guidance and significant contributions to the Corn Hybrid Evaluation Program at the University of Wisconsin-Madison. His dedication, expertise, and passion for corn agronomy have greatly enriched our research initiatives and positively impacted the agricultural community. We wish him all the best in his retirement and future endeavors.
